ABSTRACT

In this paper we analyze the suitability and feasibility of the method proposed by Prakash for the determination of the dielectric relaxation parameters, namely activation energy and fundamental relaxation time, and order of kinetics, of a thermally stimulated depolarization (TSD) spectrum, also known as ionic thermocurrent (ITC) spectrum, by applying it both to numerically generated TSD spectrum of hypothetical system and experimentally reported TSD spectrums of AgCl:Pb$^{2+}$ and KI:S$^{2-}$. It is found that the method is simpler, convenient and can be used for the analysis of TSD spectrum or ITC spectrum involving any order of kinetics.

Keywords: Dielectric relaxation parameters, Order of kinetics, Thermally stimulated depolarization, Ionic thermocurrent.

INTRODUCTION

The specimen of alkali halide matrix having impurity vacancy (IV) dipoles gets polarized in the presence of an electric field. With the electric field still on, if the specimen is rapidly cooled down to a fairly low temperature, where the relaxation time is very large or practically infinite, IV dipoles are frozen-in in the crystalline lattice and remain polarized even after switching off the electric field. If the specimen is heated at a constant linear heating rate, a stage comes when frozen-in polarized dipoles start depolarizing. Consequently, thermally stimulated depolarization current (TSDC) or ionic thermocurrent (ITC) starts appearing. The plot of thermally stimulated depolarization current as a function of temperature is known as TSD spectrum or ITC spectrum. TSDC or ITC technique is employed to determine the characteristic dielectric dielectric relaxation parameters, namely activation energy ($E_a$) and fundamental relaxation time ($\tau_o$) of specimen. There are several methods for this, as reported in literature suggested by different workers engaged in the same work, and the technique has been employed successfully. Most of the already existed methods focus on evaluation of dielectric relaxation parameters, only few methods are focused on order of kinetics parameter also [1,2]. In all the discussed methods, there are some anomalies, like few of them are not concerned with order of kinetics, few of them are suitable only for monomolecular or first order kinetics, few of them have suggested different methods for different order of kinetics and most of them are not interested whether the evaluated values of dielectric relaxation parameters ($E_a$ and $\tau_o$) satisfies equation of peak temperature. Starting from the basic idea that ITC curve corresponding to monomolecular kinetics is very much similar to a thermoluminescence (TL) glow curve involving monomolecular kinetics[3], and TL glow curves involving second and higher order kinetics [4-8] have already been reported in the literature. It was hence thought proper by Prakash [9] to assess the involvement of second and higher order kinetics in ITC spectra. ITC technique has emerged as an effective and very useful tool [3] for studying the reorientational behavior of dipoles because of its sensitivity, accuracy and convenience.
2. Prakash method of analysis

Following Prakash [9] the expression for ionic thermocurrent (I) involving general order kinetics is given by

\[ I = \frac{Q_0}{\ell \tau_0} \exp\left(-\frac{E_a}{kT}\right) - \frac{1}{b \ell \tau_0} \int_0^T \exp\left(-\frac{E_a}{kT'}\right) dT' \] (1)

where \(Q_0\) is the total charge released during ITC run, \(\ell\) is order of kinetics involved, \(k\) the Boltzmann’s constant, \(T\) the absolute temperature, \(b\) is linear heating rate, \(T_0\) is the temperature wherefrom ITC spectrum starts to appear and \(T'\) any temperature between \(T_0\) and \(T\). Equations for ITC spectra involving first, second or higher order can be obtained from above equation after substituting the corresponding value of \(\ell\) into it.

Total released charged during ITC run is given by

\[ Q_o = \frac{1}{b} \int_{T_0}^\infty I(T')dT' \] (2)

and charge released in ITC run in between temperature range \(T\) to \(\infty\) is given by

\[ Q = \frac{1}{b} \int_T^\infty I(T')dT' \] (3)

\(Q_o\) and \(Q\) can be obtained from ITC spectrum using eqs.(2) and (3) respectively.

Equations for remaining polarization \(P\) and current density \(J\) at temperature \(T\) in specimen is given by [9]

\[ P = P_o \exp\left[-\frac{1}{b \ell \tau_0} \int_{T_0}^T \exp\left(-\frac{E_a}{kT'}\right) dT'\right] \] (4)

and

\[ J = \frac{P_o}{\ell \tau_0} \exp\left(-\frac{E_a}{kT'}\right) - \frac{1}{b \ell \tau_0} \int_0^T \exp\left(-\frac{E_a}{kT'}\right) dT' \] (5)

where \(P_o\) is the maximum polarization or initial polarization.

In order to establish a method for the analysis of TSD or ITC spectrum with a view to determine dielectric relaxation parameters and order of kinetics, Prakash has considered the mechanisms responsible for the TSD or ITC processes. It has been established that the dielectric relaxation parameters, activation energy \(E_a\) and fundamental relaxation time \(\tau_o\), are characteristic features of the specimen and does not depend anyway on experimental conditions of polarization and rate of rapid cooling. However, the experimental conditions of polarization and rate of rapid cooling are the prime parameters which decide the involvement of different order of kinetics in TSD or ITC spectrum. The analysis of TSD or ITC spectra of same specimen under different experimental conditions of polarization and rate of rapid cooling results in same value of \(E_a\) and \(\tau_o\). Thus the evaluated values of \(E_a\) and \(\tau_o\) correspond to an TSD or ITC spectrum of first order kinetics and remain unaffected with either number of IV dipoles per unit volume or order of kinetics \(\ell\). The order of kinetics \(\ell\) does not represent the characteristic feature of the system under consideration. The experimentally reported data for single crystal [3] KCl: Sr\(^{2+}\) support this statement.

Thus, \(E_a\) and \(\tau_o\), are the characteristic dielectric relaxation parameters of the system and are found to be independent of the order of kinetics and experimental conditions. Hence, these parameters can be obtained from eq.(1) after substituting \(\ell = 1\) in it. In such a case eq.(1) with the help of eqs.(4) and (5) for \(\ell = 1\) can be written as

\[ I = \frac{Q_o}{\tau_o} \exp\left(-\frac{E_a}{kT}\right) \] (6)

which can be rearranged as

\[ \ln\left(\frac{Q}{T}\right) = \ln(\tau_o) + \frac{E_a}{kT} \] (7)

From eq.(7) it is obvious that when \(\ln\left(\frac{Q}{T}\right)\) plotted against \(\left(\frac{1}{T}\right)\) will give a straight line. The slope and intercept of the straight line give the values of \(E_a\) and \(\tau_o\), respectively. Knowing the values of \(E_a\) and \(\tau_o\), order of kinetics \(\ell\) can be obtained from equation of peak temperature \(T_m\), given by
3. Analysis of TSD spectrum

In above discussion it is clear that, in order to determine dielectric relaxation parameters by Prakash method, one has to evaluate \( \frac{Q}{I} \) which is given by the area of a TSD spectrum from the temperature under consideration until the end point and corresponding current.

3.1. Analysis of experimentally reported TSD spectrums

Following the method suggested by Prakash, experimentally observed TSD spectrums, already reported in literature, of specimens AgCl:Pb\(^{2+}\)\[11\] and KI:S\(^{2-}\)\[12\] are analyzed and the results are given below:

Data collected from already reported TSD spectrum of specimen AgCl:Pb\(^{2+}\)[11] are given in Table.1. As per the eq.(7) plot of \( \ln(Q/I) \) vs 1/T is shown in Fig.1. From experimentally reported spectrum, \( T_m = 112.3K \), \( I_m = 1.796E-13A \), \( b = (1/30)K/s \), \( Q_0 = 4.872E-09\) C. Boltzman’s constant \( k = 8.617E-5\ eV/K \). From Fig.1 slope = 4348.2 and intercept = -29.9. Using eqs.(7), (8) and (9) calculated values of different parameters are as given below:

(i) Activation Energy \( E_a = 0.3746885\ eV \),
(ii) Fundamental Relaxation Time \( \tau_o = 1.06851E-13\ s \) and
(iii) Order of Kinetics \( \ell = 0.01244336\).

Data collected from already reported TSD spectrum of specimen KI:S\(^{2-}\)[12] are given in Table.2. As per the eq.(7) plot of \( \ln(Q/I) \) vs 1/T of Specimen KI:S\(^{2-}\) is shown in Fig.2.

From experimentally reported spectrum, \( T_m = 204 \)K, \( I_m = 3.6E-13 \)A, \( b=0.05 \)K/s, \( Q_0 = 1.922E-09 \) C. Boltzman’s constant \( k = 8.617E-5 \) eV/K. From Fig.2 slope = 4987.864 and intercept = -16.9002. Using eqs.(7), (8) and (9) calculated values of different parameters are as given below:

(i) Activation Energy \( E_a = 0.429804243 \) eV,
(ii) Fundamental Relaxation Time \( \tau_o = 4.57442E-08 \) s and
(iii) Order of Kinetics \( \ell = 0.087781491 \).

3.2. Analysis of hypothetically generated TSD spectrum
Here we consider a hypothetical system with \( E_a = 0.60 \) eV, \( \tau_o = 5.0 \times 10^{-13} \) s, \( Q_o = 3.0 \times 10^{11} \) C and \( b = 0.05 \) Ks⁻¹ and plot current versus temperature curve for different values of order of kinetics \( \ell \) in accordance with eq.(1). The resulting TSD spectrum is shown in Fig.3. According to equation (7) a single straight line is obtained, as shown in Fig.4, for all the curves of Fig.3 particularly because of the fact that dielectric relaxation parameters and \( Q_o \) are same for them and slope and intercept evaluated using eq. (7) do not depend on \( Q_o \). It is due to this reason that a single straight line results in Fig 4. The slope and intercept of the straight line give the values of dielectric relaxation parameters \( E_a \) and \( \tau_o \), respectively. Knowing the values of \( E_a \) and \( \tau_o \), order of kinetics can be obtained using eqs. (8) and (9). The values are same as assumed for hypothetical system.
CONCLUSION

In the present paper we have analyze experimentally reported TSD spectrums of different specimen and numerically generated TSD spectrum of hypothetical system, and evaluate all the three parameters $E_a$, $s$ and $\ell$, following the Prakash method. This method for the evaluation of dielectric relaxation parameters $E_a$ and $\tau_o$ is in fact BFG method [3] represented through eqs. (7). Consequently, the accuracies associated with the evaluation of $E_a$ and $\tau_o$ shall be the same as that obtained in BFG method. It is obvious that the Prakash method is simpler and convenient for the evaluation of dielectric relaxation parameters. No simplifying assumptions have been incorporated by Prakash in developing eq. (1). Activation energy and relaxation time are characteristic features of the specimen and unaffected by the experimental conditions. The experimental conditions of polarization for getting frozen-in polarized dipoles decide the order of kinetics involved. It is because of this reason that different TSD runs recorded on the same specimen give different values of order of kinetics. Further, the dependence of peak temperature $T_m$ on $Q_o$ is also excluded in the suggested model.

Fig.3: TSD spectra involving different order of kinetics for a hypothetical system with $E_a = 0.60$ eV, $\tau_o = 5.0 \times 10^{-13}$ s, $Q_o = 3.0 \times 10^{-11}$ C and $b = 0.05$ ks$^{-1}$. the number on the curves represents the involved order of kinetics
